Keywords: Manganese oxide Octahedral molecular sieves (OMS-2) Catalytic oxidation VOCs Lattice oxygen

ABSTRACT

OMS-2 nanorod catalysts were synthesized by a hydrothermal redox reaction method using MnSO₄ (OMS-2-SO₄) and Mn(CH₃COO)₂ (OMS-2-AC) as precursors. SO₄²⁻-doped OMS-2-AC catalysts with different SO₄²⁻ concentrations were prepared next by adding (NH₄)₂SO₄ solution into OMS-2-AC samples to investigate the effect of the anion SO_4^{-} on the OMS-2-AC catalyst. All catalysts were then tested for the catalytic oxidation of ethanol. The OMS-2-SO₄ catalyst synthesized demonstrated much better activity than OMS-2-AC. The SO_4^{-1} doping greatly influenced the activity of the OMS-2-AC catalyst, with a dramatic promotion of activity for suitable concentration of SO_4^{2-} (SO₄/catalyst = 0.5% W/W). The samples were characterized by X-ray diffraction (XRD), field emission scanning electron microscopy (FE-SEM), transmission electron microscopy (TEM), X-ray photoelectron spectroscopy (XPS), inductively coupled plasma optical emission spectroscopy (ICP-OES), NH₃-TPD and H₂-TPR techniques. The results showed that the presence of a suitable amount of SO₄²⁻ species in the OMS-2-AC catalyst could decrease the Mn–O bond strength and also enhance the lattice oxygen and acid site concentrations, which then effectively promoted the catalytic activity of OMS-2-AC toward ethanol oxidation. Thus it was confirmed that the better catalytic performance of OMS-2-SO₄ compared to OMS-2-AC is due to the presence of some residual SO₄²⁻ species in OMS-2-SO₄ samples.

Introduction

Volatile organic compounds (VOCs) are major organic pollutants in the atmosphere and are very harmful to human health (Jacobson, 2007). Industrial pollution and vehicle emissions are the main sources of VOCs. Ethanol is a widely used solvent and an important fuel supplement for vehicles, and has been recognized as one of the major contributors to VOC pollution (Poulopoulos et al., 2001). Therefore, it is of great importance to develop an effective method for ethanol elimination. Catalytic oxidation is considered to be the most effective technology for this purpose, because VOCs can be oxidized to CO_2 over certain catalysts at much lower temperatures than in thermal oxidation. There are two main types of conventional catalysts used for ethanol oxidation reactions: noble metals (Avgouropoulos et al., 2006; Mitsui et al., 2008; Tang et al., 2005) and metal oxides (Idriss and Seebauer, 2000; Li et al., 2011; Ye et al., 2006; Trawczyński et al., 2005; Luo et al., 2000). Taking account of economic factors and catalytic properties, recent studies on catalytic oxidation of ethanol have been more focused on metal oxide-based catalysts.

Manganese oxides, especially OMS (octahedral molecular sieve) oxides, have many intrinsic advantages as oxidation catalysts, since OMS oxides have a variety of 3D structures (such as OL-1, OMS-1, OMS-2, *etc.*), and Mn atoms are present in various oxidation states (Mn^{4+} , Mn^{3+} , Mn^{2+}) in these

structures (Suib, 2008; Wang et al., 2012). The OMS-2 structure comprises a peculiar sharing of 2×2 [MnO₆] octahedral chains that form one-dimensional tunnel structure with a pore size of 0.46 nm × 0.46 nm. OMS-2 catalysts have been found to be particularly effective in ethyl acetate (Gandhe et al., 2007), benzyl alcohol (Makwana et al., 2002) and benzene (Luo et al., 2000) oxidation compared with other OMS materials. A great deal of research has been carried out to improve the catalytic activity of OMS-2 by various means, such as using different preparation methods (Malinger et al., 2006), incorporation of metal cations into the OMS-2 tunnel (Chen et al., 2002) and using different precursors (Wang and Li, 2010). Alkali metal cations and NH⁺₄ cations have been used as the templates to synthesize 2×2 tunnel structures (A-OMS-2; A = Li, Na, K Rb, or NH_4^+). It was found that the nature of the cations affects the crystallinity, microstructure, and properties of these materials such as the surface area, thermal stability, and chemical composition (Liu et al., 2003). Hou et al. (2014) recently reported that increasing the K⁺ concentration could greatly enhance the lattice oxygen activity of OMS-2 nanorod catalysts, thus significantly increasing the catalytic activity for benzene oxidation. The precursor of OMS-2 was also found to have a big influence on the activity. Wang and Li (2010) observed that OMS-2(S), prepared using MnSO₄ as precursor, exhibited better catalytic performance in ethanol oxidation than OMS-2(AC), with Mn(CH₃₋ COO)₂ as precursor, and they attributed this to the weaker Mn-O bond in OMS-2(S), resulting in more lattice defects and labile lattice oxygen. However, they did not discuss the factor in OMS-2(S) that induces this weaker Mn-O bond.

It is known that SO₄²⁻ treatment of catalysts can change the catalytic behavior significantly in some cases. It has been reported that the addition of SO_4^{2-} enhanced the activity of MoOx and VOx/TiO₂ for the reduction of NO with NH₃ or H₂. Wang et al. (2011) recently also found that the sulfation of Zr-Co hydroxides induced higher activity in Pd/ZC catalysts for CH₄-SCR of NOx. The positive effect of SO₄²⁻ on the activity was mainly ascribed to the change in acidity on the catalyst surface. It is also well known that the acidic properties of mixed oxide catalysts play an important role in the catalytic oxidation of hydrocarbons, and strong acidity could generally facilitate the breaking of carbon-carbon bonds and promote CO₂ production (Rajesh and Ozkan, 1993). Therefore, we proposed that the anion SO_4^{2-} may also have a great influence on OMS-2 activity, and that the better performance of OMS-2(S) for ethanol oxidation compared to OMS-2(AC) is possibly related to the presence of SO_4^{2-} species.

Herein, OMS-2 catalysts were first synthesized by a hydrothermal method using $MnSO_4$ and $Mn(CH_3COO)_2$ as the precursors. The OMS-SO₄ catalyst ($MnSO_4$ precursor) exhibited better catalytic performance than the OMS-2-AC catalyst ($Mn(CH_3COO)_2$ precursor). We next prepared SO_4^{2-} -doped OMS-2-AC catalysts with different SO_4^{2-} concentrations to investigate the effect of the anion SO_4^{2-} on the OMS-2-AC catalyst for ethanol oxidation. It was demonstrated that a suitable SO_4^{2-} concentration could dramatically promote the activity of the OMS-2-AC catalyst. In addition, the samples were characterized by several methods, and the mechanism of the promoting effect of sulfation on the OMS-2 catalyst was also elucidated. Based on the obtained results, we confirmed

that the better catalytic performance of OMS-2-SO₄ compared to OMS-2-AC is due to the presence of some residual SO_4^{2-} species in the OMS-2-SO₄ sample.

1. Experimental

1.1. Catalyst preparation

OMS-2 catalysts were prepared by a hydrothermal method that mainly depends on self-redox between Mn^{7+} (KMnO₄) and Mn^{2+} (2 MnO_4^- (aq) + 3 Mn^{2+} (aq) \rightarrow 5 MnO_x (s)). $Mn(CH_3COO)_2$ and $MnSO_4$ were used as precursors to provide the Mn^{2+} source. The KMnO₄ solution was added into a Mn^{2+} solution (Mn(CH₃COO)₂ or MnSO₄) at a MnO_4^-/Mn^{2+} molar ratio of 0.78, then 2 mL nitric acid was added to adjust the pH value. The mixed solution was stirred for 1 hr and then placed in a Teflon liner and sealed in a stainless-steel vessel, and a hydrothermal treatment was performed at 100°C for 24 hr. The product was separated by filtration, washed several times with deionized water and dried at 100°C overnight. All the samples were calcined at 400°C in air for 2 hr. The as-prepared catalysts are designated as OMS-2-AC and OMS-2-SO₄, respectively.

In order to assess the influence of sulfation species on activity, SO_4^{2-} -doped OMS-2 was next obtained by adding a $(NH_4)_2SO_4$ solution into OMS-2-AC samples. 3.0 g OMS-2-AC catalyst was mixed with 30 mL distilled water in a beaker, then 12.4, 20.6, 41.2, or 82.4 mg of $(NH_4)_2SO_4$ was added into the solution under vigorous magnetic stirring for 1 hr, and dried at 100°C overnight. All the samples were calcined at 400°C in air for 2 hr. The results of inductively coupled plasma-optical emission spectroscopy (ICP-OES, Optima-2000DV, PerkinElmer Co, Waltham, Massachusetts, USA) measurements (determined by elemental analysis of S) showed that the SO_4^{2-} loading was 0.3, 0.5, 1.0, and 2.0 wt.%, respectively, and the catalysts are hereinafter designated as 0.3%, 0.5%, 1.0%, and 2.0% SO₄-OMS-AC.

1.2. Material characterizations

The samples were characterized structurally by X-ray diffraction (XRD, X'Pert Pro, PANalytical Co, Almelo, Holland), using a Bruker D8 Advance Diffractometer with a monochromatic Cu Ká source operated at 40 kV and 40 mA. The diffraction patterns were taken at room temperature in the range of $10 < 2\dot{e} < 90^{\circ}$. For phase identification purposes, the JCPDS database of reference compounds was used. Surface area and pore volume were measured using a Quadrasorb system (Autosorb-IQ-1MP, Quantachrome Co, Boynton Beach, Florida, USA) at liquid nitrogen temperature (77 K). Transmission electron microscopy (TEM, JEM-2011LaB6, JEOL Ltd., Tokyo, Japan) images were obtained with a JEOL JEM-2011LaB6 at an accelerating voltage of 200 kV. The samples were ultrasonically suspended in ethanol and deposited on a copper grid covered with a thin layer of holey carbon. The field-emission scanning electron microscopy (FE-SEM, S-3000N, Hitachi Ltd., Tokyo, Japan) images were taken using a SU-8020 scanning electron microscope. The samples for FE-SEM measurements were prepared by depositing the powder on graphite tape.

ICP-OES (inductively coupled plasma optical emission spectroscopy, Prodigy XP, Leeman LABS, Hudson, New Hampshire, USA) was carried out as follows. 100 mg of sample was dissolved in concentrated hydrochloric acid at 90°C for 4 hr, at which point no solid remained. The concentrated liquid was diluted to an appropriate concentration and then analyzed by a programmable array detector.

X-ray photoelectron spectroscopy (XPS, PHI Quantera, ULVAC-PHI Inc., Kanagawa, Japan) data were obtained with an electron spectrometer (AXIS Ultra, Kratos Analytical, Inc., Manchester, UK) with Al Ká radiation at a pressure lower than 10^{-7} Pa. The binding energies were referenced to the C 1s line at 284.8 eV from adventitious carbon. The spectra were calculated using the XPSPEAK program by curve fitting with a Gaussian/Lorentzian ratio of 90/10 after smoothing and subtraction of the Shirley-type background.

H₂ temperature programmed reduction (H₂-TPR) and ammonia temperature programmed desorption (NH₃-TPD) were performed in an apparatus (AutoChem II 2920, MICROMERITICS INSTRUMENT, Norcross, GA, USA) equipped with a computer-controlled CryoCooler and a thermal conductivity detector (TCD). H₂-TPR profiles were obtained by passing a flow of 10% H₂/Ar at a rate of 50 mL/min (STP) through the sample (weight around 30 mg). The temperature was increased from 50 to 1000°C at a rate of 10°C/min, and the H₂ consumption was monitored by TCD after removal of produced H₂O. For NH₃-TPD, 100 mg of the samples were first pre-heated in air at 300°C for 30 min. After preheating, ammonia adsorption was carried out at 40°C for 90 min by passing a gas mixture of 260 ppm ammonia in Argon over the sample at a flow rate of 50 mL/ min. The sample was then flushed with 60 mL/min Argon to remove the surface physisorbed ammonia. After flushing, the sample was heated under a flow of Argon from 50 to 900°C with a temperature ramp of 10°C/min.

1.3. Catalytic evaluation

Activity tests for the catalytic oxidation of ethanol over the catalysts (~50 mg) were performed in a fixed-bed quartz flow reactor with a gas mixture containing 800 ppm ethanol, 20% O_2 and N_2 balance at a total flow rate of 100 mL/min (gas hourly space velocity (GHSV) = 36,000 hr⁻¹). The reactants and the reaction products of a possible incomplete reaction were analyzed by using an on-line gas chromatograph (GC-6890N, Agilent Technologies, Santa Clara, CA, USA) equipped with a Porapak Q column for the analysis of ethanol, CO_2 , and acetaldehyde, and quantified by using a TCD. The temperatures were measured with a thermocouple, and the data reported at each reaction temperature were the average of at least two steady-state measurements.

2. Results

2.1. Catalytic activity

The as-prepared OMS-2-SO₄ and OMS-2-AC catalysts were evaluated for the oxidation of ethanol. Fig. 1a and b exhibits the ethanol conversion and the acetaldehyde yield over the catalysts as a function of reaction temperature, with an inlet ethanol concentration of 800 ppm and a GHSV of 36,000 hr^{-1} , respectively. As shown in Fig. 1a, the OMS-2-SO₄ catalyst

Fig. 1 – (a) Ethanol conversion performance of different catalysts; (b) acetaldehyde yield of OMS-2-SO₄, 0.5% SO₄-OMS-AC and OMS-2-AC catalysis during ethanol oxidation; (c) ethanol conversion on 0.5% SO₄-OMS-AC with time on stream at 110°C. Reaction conditions: 800 ppm ethanol, 20 vol.% O₂, and N₂ as balance gas; gas hourly space velocity 36,000 hr⁻¹. Different catalysts refer to Section 1.1.

showed much better performance than the OMS-2-AC catalysts. 100% ethanol conversion was achieved at 120°C over OMS-2-SO₄ and at 180°C over the OMS-2-AC catalyst, respectively. As shown in Fig. 1b, acetaldehyde is the major by-product during the ethanol oxidation process, and 100% CO_2 yield was obtained at 140°C over OMS-2-SO₄, while it was still not fully achieved at 180°C over the OMS-2-AC catalyst. Compared with previously reported OMS-2 catalysts, the as-prepared OMS-2-SO₄ catalyst is more active than MnOx

catalysts synthesized by an exotemplating method (Bastos et al., 2009) and other OMS-2 material prepared by a refluxing method (Wang and Li, 2010), and is even superior to Pt/Al_2O_3 catalysts (Avgouropoulos et al., 2006).

The SO₄²⁻-doped OMS-2-AC materials were tested next, and the results are also shown in Fig. 1a. When the SO_4^{2-} amount was increased from 0.3% to 0.5%, the catalytic activity of OMS-2-AC was clearly enhanced, and the profile of ethanol conversion shifted to a lower temperature range. However, further increasing the SO_4^{2-} amount to 1.0% and 2.0% resulted in a sharp drop in ethanol conversion. It is clear that the 0.5% SO₄-OMS-AC showed the best performance, which is almost equal to that of the OMS-2-SO₄ sample. The above results indicated that a suitable amount of SO_4^{2-} modification could significantly promote the activity of the OMS-2-AC material; however, too much SO_4^{2-} species would act as a poison to the catalyst. In addition, these results also demonstrated that the much higher activity of the OMS-2-SO₄ sample compared to OMS-2-AC is possibly due to the presence of SO_4^{2-} in this sample. The catalytic performance of the 0.5% SO₄-OMS-AC catalyst was also checked by long isothermal tests. As shown in Fig. 1c, approximately 80% ethanol conversion was maintained over a 60 hr-long test, demonstrating the excellent stability of this catalyst.

2.2. XRD and BET tests

(110)

(200)

Fig. 2 shows the XRD patterns of OMS-2-SO₄, OMS-2-AC and SO_4^{2-} -modified OMS-2-AC samples. The (101), (002), (301), (211), (310), (114) and (600) reflections at 2è = 12.7, 18.0, 28.7, 37.5, 41.8, 50.0 and 56.2° were observed, revealing that all the as-synthesized samples can be indexed to the pure tetragonal cryptomelane structure of OMS-2 (KMn₈O₁₆, JCPDS34-168). In addition, when the SO₄²⁻ amount was 0.3% and 0.5%, no SO_4^{2-} -related XRD peaks were observed, showing that SO_4^{2-} species are highly dispersed on the catalyst or incorporated into the lattice of OMS-2-AC samples. However, when the SO_4^{2-} amount was 1.0% and 2.0%, excessive SO_4^{2-} resulted in the appearance of a weak MnSO₄ peak (JCPDS 3–810) at 32.8°.

The BET surface area and pore parameters are presented in Table 1. The OMS-SO₄ catalyst showed a slightly higher

surface area and pore volume, and similar BJH pore diameter compared to the OMS-2-AC catalyst. The 0.5 wt.% SO_4^{-1} addition to OMS-2-AC did not induce any obvious change to the above-mentioned parameters. The contents of SO_4^{2-1} in OMS-2-SO₄, OMS-2-AC and SO_4^{2-1} -modified OMS-2-AC samples were measured by ICP-OES, and the results are also presented in Table 1. When using MnSO₄ as precursor, about 0.5 wt.% residual sulfation species remained on OMS-2-SO₄ samples. No SO_4^{2-1} species were detected when using MnAC as precursor. After doping 20.6 mg (NH₄)₂SO₄ into 3 g OMS-2-AC samples, about 0.5 wt.% SO_4^{2-1} species was found to be loaded, showing minimal loss of SO_4^{2-1} species during the preparation.

2.3. XPS results

OMS-2-AC

The chemical states of OMS-2-SO₄, OMS-2-AC and 0.5% SO₄-OMS-AC catalysts were determined by XPS and the results are presented in Table 2. Only Mn^{4+} species were detected, at binding energies around 642.4 eV (Mn $2p_{3/2}$) and 654.1 eV (Mn $2p_{1/2}$). No XPS peaks of other Mn species were observed. This suggests that manganese species were present predominantly as MnO_2 in all the samples (Liang et al., 2008). In addition, the results above indicated that the use of different precursors and the 0.5% SO₄²⁻ doping did not change the binding energy of Mn 2p.

The O 1s spectra for all the samples presented two peaks $(O_{\alpha} \text{ and } O_{\beta})$ with BE values at 529.8 and 532.2 eV. The peak at 532.2 eV may be assigned to less electron-rich surface oxygen species (O_{α}) , and another peak at 529.8 eV was ascribed to the lattice oxygen species $O_2^ (O_{\beta})$ (Wang and Li, 2010). The O_{β} concentrations were calculated and are summarized in Table 2. It is shown that the OMS-SO₄ catalyst contained 72% O_{β} species, which is higher than that in the OMS-2-AC catalyst (64%). Interestingly, doping 0.5% SO₄²⁻ species into OMS-2-AC samples clearly increased the O_{β} concentrations from 64% to 68%, indicating that the higher O_{β} concentration in the

OMS-2-SO₄ catalyst is possibly due to the presence of some residual SO_4^{2-} species.

2.4. SEM and TEM results

The morphologies of OMS-2-SO₄, OMS-2-AC and 0.5% SO₄-OMS-AC samples were investigated by FE-SEM and HR-TEM, and the samples images are shown in Fig. 3. The FE-SEM results revealed that all of the samples are characterized by a nanorod morphology. High-resolution TEM (HRTEM) images indicated that all of the OMS-2 samples exhibited a single crystal structure with an exposed {200} facet (Yuan et al., 2005). These results showed that the use of different precursors and the 0.5% SO₄²⁻ doping had no influence on the morphology of the OMS-2 catalysts.

2.5. NH₃-TPD results

The surface acidity of mixed oxide catalysts is known to play an important role in the catalytic oxidation of hydrocarbons, and the presence of strong acidity could generally facilitate the breaking of carbon-carbon bonds and promote CO_2 production (Rajesh and Ozkan, 1993). Therefore, the surface acidity of OMS-2-SO₄, OMS-2-AC and 0.5% SO₄-OMS-AC samples was next

measured by the NH₃-TPD method, and the results are shown in Fig. 4 and Table 3. As shown in Fig. 4, the three samples have obvious NH₃ desorption in the temperature range of 75–300°C. The OMS-2-AC and 0.5% SO₄-OMS-AC samples had a single kind of acid site, with the maximum of the desorption peak occurring at around 120°C. In contrast, the OMS-2-SO₄ sample also presented a strong acid site at around 120°C, but had an additional small shoulder peak at around 250°C, indicating that the OMS-2-SO₄ catalyst had an additional stronger kind of acid site compared with the OMS-2-AC catalyst. The concentrations of acid sites based on the NH3-TPD results are presented in Table 3. It is shown that the OMS-2-SO₄ catalyst contained 79.9 µmol/g acid sites, much more than the OMS-2-AC catalyst (65.5 imol/g). Clearly, doping 0.5% SO₄²⁻ species into OMS-2-AC samples enhanced the acid sites from 65.5 to 81.9 imol/g, indicating that the presence of residual SO_4^{2-} species is responsible for the higher concentration of acid sites on OMS-2-SO₄ than on the OMS-2-AC catalyst, therefore benefiting the catalytic oxidation of ethanol.

2.6. H₂-TPR results

The redox characteristics of catalysts were next studied by means of TPR experiments. Fig. 5 illustrates the H_2 -TPR

Fig. 3 – FE-SEM (field emission scanning electron microscopy) and HR-TEM (high-resolution transmission electron microscopy) images of as-synthesized OMS-2-AC (a–c), OMS-2-SO₄ (d–f) and 0.5% SO₄-OMS-AC (g–k).

Fig. 4 – NH₃-TPD profiles of OMS-2-SO₄, OMS-2-AC and 0.5% SO₄-OMS-AC catalysts.

2.7. Mn–O bond and lattice oxygen

The Mn–O bond of OMS-2 catalysts was found to play an important role in determining their catalytic activity in VOC oxidation (Li et al., 2010). Therefore, the Raman spectra of OMS-2-SO₄, OMS-2-AC and 0.5% SO₄-OMS-AC samples were measured next to investigate the deformation modes of the Mn–O–Mn bond, and the results are shown in Fig. 6. All samples presented two clear bands at 586 and 647 cm⁻¹, which correspond to the stretching modes of the Mn–O lattice

Fig. 5 – H_2 -TPR profiles of OMS-2-SO₄, 0.5% SO₄-OMS-AC and OMS-2-AC catalysts.

(Wang and Li, 2010). The peak widths and intensities of OMS-2-SO₄ were much greater than those of OMS-2-AC, indicating that the Mn–O lattice bond in OMS-2-SO₄ was in a more highly distorted state, with more crystal defects in the catalyst, than that in the OMS-2-AC sample. The doping of 0.5% SO_4^{2-} species into OMS-2-AC samples clearly increased the peak widths and intensities of OMS-2-AC, demonstrating that the presence of SO_4^{2-} species is responsible for the more highly distorted state of Mn–O in the OMS-2-SO₄ catalyst. It was reported that sulfation could induce the crystalline transformation of ZrO_2 by the interaction of SO_4^{2-} species with O atoms (Haase and Sauer, 1998). We estimated that SO₄²⁻ species in OMS-2-SO4 or 0.5% SO4-OMS-AC samples had a strong interaction with nearby Mn atoms, which can affect the Mn-O bond strength. This then weakened the Mn-O bond and produced more lattice defects and a more labile lattice, leading to the better activity of OMS-2-SO₄ in ethanol oxidation.

3. Conclusions

In this work, we demonstrated that SO_4^{-} doping has a great influence on OMS-2-AC catalysts in the catalytic oxidation of ethanol. We found that doping a suitable amount of SO_4^{-} species into the OMS-2-AC catalyst could decrease the Mn–O bond strength and also enhance the lattice oxygen concentration and number of acid sites, which then effectively promoted the catalytic activity of OMS-2-AC. Thus, it is confirmed that the better catalytic performance of OMS-2-SO₄ compared to OMS-2-AC is closely related to the presence of some residual SO_4^{-} species in OMS-2-SO₄ samples.

Table 3 – H_2 and NH_3 consumption of OMS-2-SO ₄ , 0.5% SO ₄ -OMS-AC and OMS-2-AC catalysts.										
Catalyst	Reduction temperature (T)		H_2 consumption			$\rm NH_3$ consumption				
	T _{low} (°C)	T _{high} (°C)	C _{low} (mmol/g)	C _{high} (mmol/g)	C _{all} (mmol/g)	Total amount (μmol/g)
